
Supplementary Appendix 6.1a. Species Incidences on Offshore Islands: Logit Regression Analyses

The analytic models and predictions for each butterfly species over all islands ($n = 910$ islands) are based on logistic regression analysis (forwards, stepwise entry) parameters for geographical and source-influence variables determined for a subset of 191 islands that have records for two or more of three long-distance migrants (variable migmark3 > 1: *Colias croceus*, *Vanessa cardui*, *Vanessa atalanta*). Predictions for two sets of logistic regressions per species are compared.

The first is based on five factors (principal components, varimax rotated, normalized) extracted from the following seven geographical variables:

- F1: island isolation (I1) and satellites (SAT);
- F2: island area (A) and maximum elevation (ELEV);
- F3: longitude (LONG);
- F4: island isolation (I2);
- F5: latitude (LAT).

The second is based on one of two contributory source variables:

- FS1: number of 10 km square records within 50 km of the nearest mainland source;
- FS2: number of 10 km square records within 50 km of the nearest larger source, island or mainland).

These variables are highly correlated for individual species across 191 islands ($r^2 > 0.7$). For any species the source selected is that producing the higher Z value from a Mann–Whitney for the 191 islands.

A. Factor Analysis of Geographical Variables

Factor extraction for geographical variables was undertaken using PCA (varimax, normalized) of seven geographical variables (excludes mainland and island source mass measures).

Species Incidences on Offshore Islands: Logit Regression Analyses

All analyses from file MAINISLANDDATA20March2017

Eigenvalues

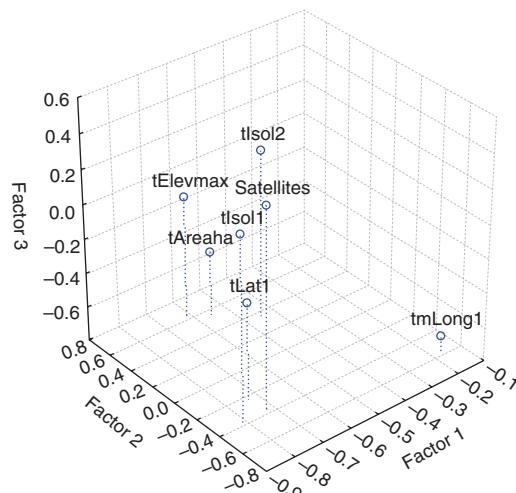

Factor extracted	Eigenvalue	% Total variance	Cumulative eigenvalue	Cumulative %

All variables but satellites are log transformed. Bold loadings indicate focus of each factor.

Factor Loadings: Factor 1 vs. Factor 2 vs. Factor 3
 Rotation: Unrotated
 Extraction: Principal components

B. Detailed Results of Species Logit Analyses

In the following pages of Supplementary Appendix 6.1a are the Mann–Whitney *U* tests and logistic regression equation parameters for each species, all those with at least ten incidences (or absences) from a selection of islands with at least two of the three migrant species. For each species, statistics are first provided for the five geographical factors; then for the best of the two source variables.

At the end of the species assessments, a set of summary statistics is provided on the findings, comparing the two sets of analyses based on geographical factors and source variables.

Supplementary Appendix 6.2 shows the predictions for species across the entire file of 910 islands. Three columns are provided for each species, in order: the observed incidence (coded: 0 absent, 1 present), the prediction based on geography factors (G Pred), and then the prediction based on the best of the two source variables (S Pred). Each species is prefixed by a code comprising the first generic letter followed by the first three species letters (e.g. *Maniola jurtina* is Mjur).

Great caution is required when interpreting these predictions. Firstly, they are *not* based on all possible variables (i.e. a selection of geography and source variables separately, *not* together). Secondly, note the odds ratio table and the level of correct predictions for the islands analysed to provide the predictions; predictions are rarely anywhere near 100% correct for known incidences. Bear in mind what has been said throughout this book: we can be more certain about the known knowns (records for islands) than the known unknowns (absences from islands). The table in Supplementary Appendix 6.2 (part 2) is mainly of value for comparing the equations for geography and source variables.

C. Relationship and Comparison of Predictions Based on Geography Factors (7 variables in 5 factors) and the Best of Two Highly Correlated Source Variables

Relationship between predictions for species over 910 islands based on the best source variable (SV) and geography factors (GF). Both variables have been log transformed.

Including *E. tages* (with a very weak model), the correlation is substantially reduced but still highly significant: see below.

Comparison of the predictions using a simple paired t-test

T-test for Dependent Samples (PredictionSummary)

Marked differences are significant at $p < .05000$

	Std. Mean	Std. Dv.	N	Diff. Diff.	Std.Dv. Diff.	t	df	p	Confidence -95.000%	Confidence +95.000%
tPredGF	4.543	1.381								
tPredSV	4.953	1.557	32	-0.4099	0.6504	-3.57	31	0.0012	-0.6444	-0.1754

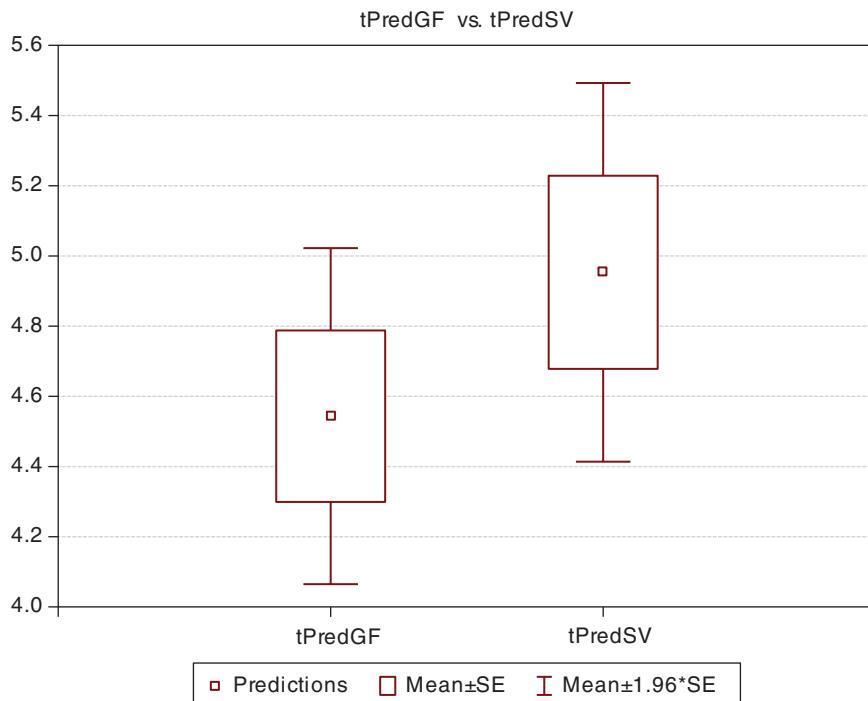

t, transformed (log); Pred, predictions (number of islands); GF, geography factors; SV, source variable. Generally, using a source variable predicts species to occur on more islands than using geography factors.

Including *E. tages* in the t-test:

T-test for Dependent Samples (PredictionSummary)

Marked differences are significant at $p < .05000$

	Std. Mean	Std. Dv.	N	Diff. Diff.	Std.Dv. Diff.	t	df	p	Confidence -95.000%	Confidence +95.000%
tPredGF	4.432	1.5450								
tPredSV	4.921	1.5433	33	-0.4897	0.8887	-3.17	32	0.003	-0.8048	-0.1746

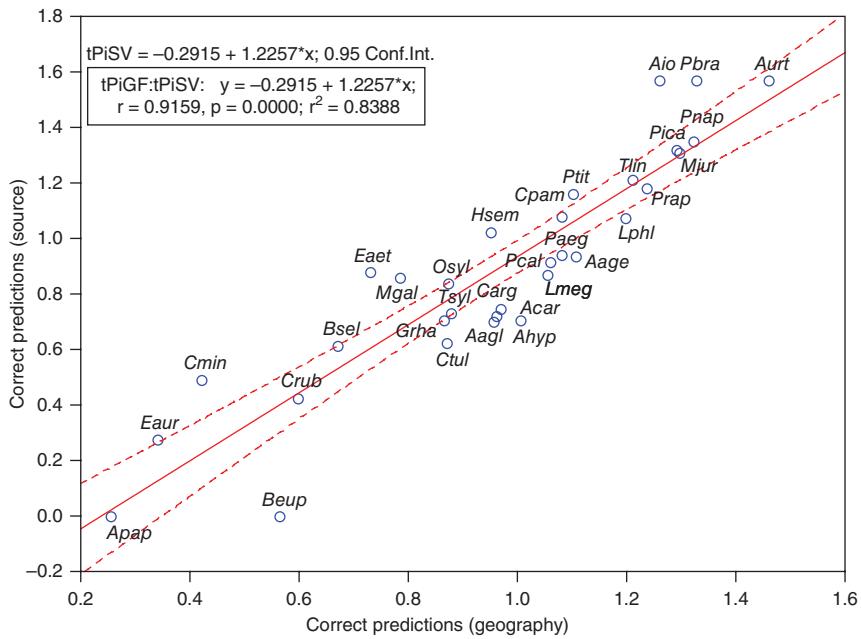

D. Relationship and Comparison of Correct Predictions of Island Incidences for 191 Islands with at least two of three migrant markers (Ccro, Vata, Vcar)

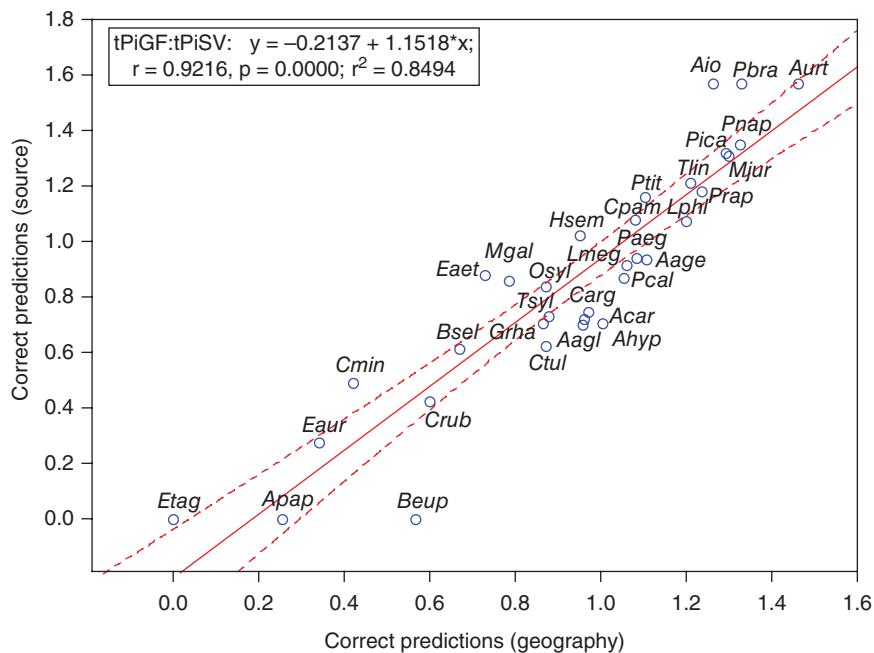

Relationship between correct predictions of recorded incidences on 191 islands with at least two of three migrant markers.

Both variables have been Arcsin(Sqrt) transformed.

tPiGF, correct predictions for incidences on geography variables;
tPiSV, correct predictions for incidence on the best source variable.

Including *E. tages*:

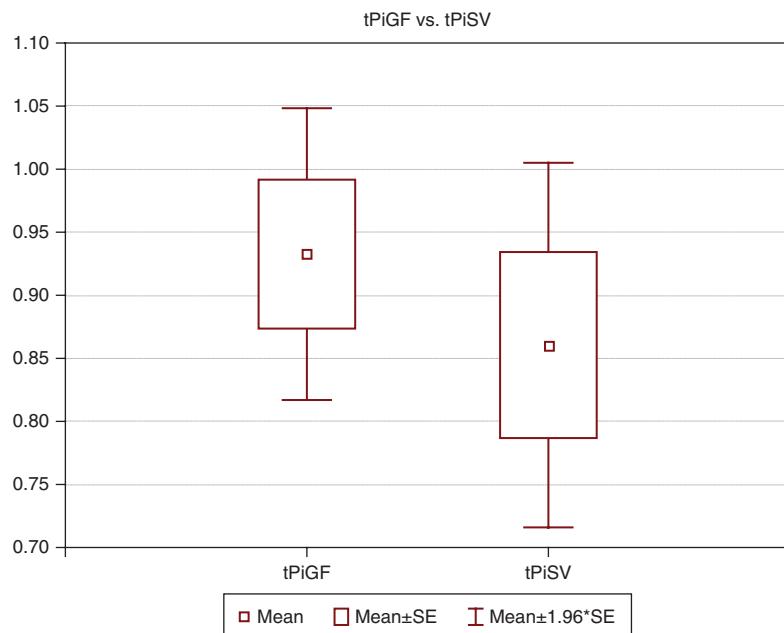

Comparison of the same predictions using a simple paired t-test

T-test for Dependent Samples (PredictionSummary)

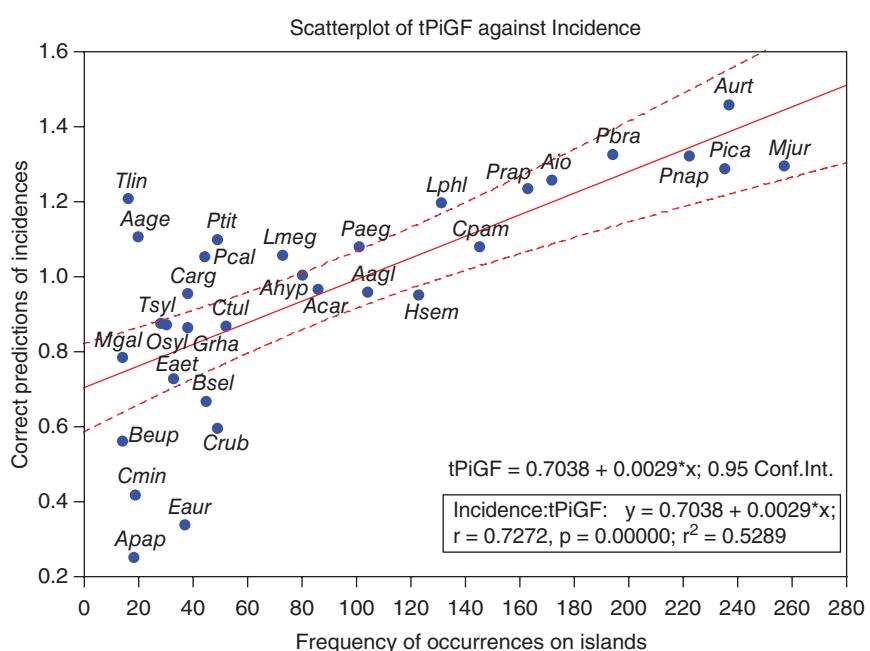

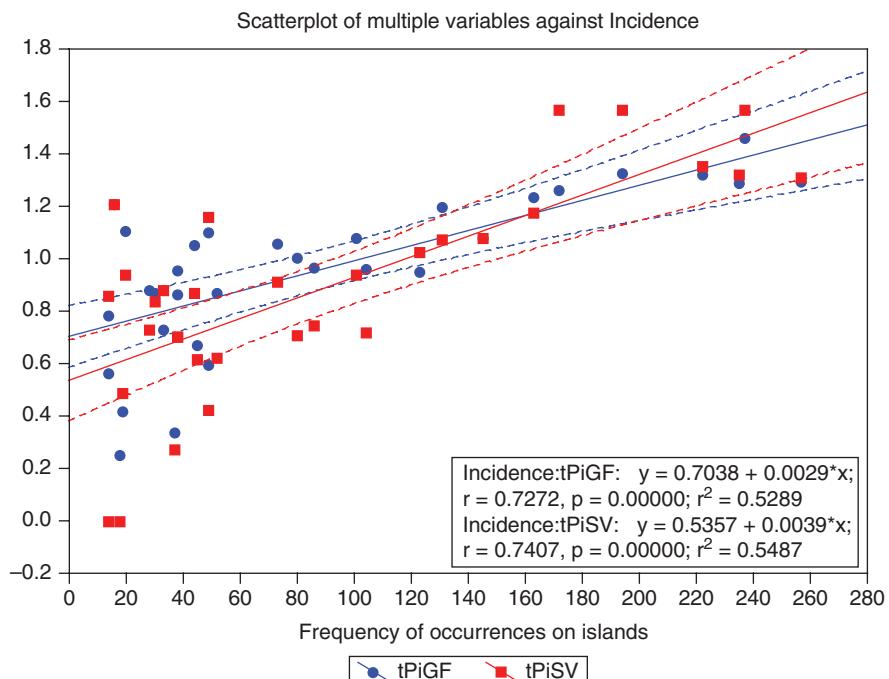

Marked differences are significant at p < .05000

	Mean	Std. Dv.	N	Diff.	Std.Dv. Diff.	t	df	p	Confidence -95.000%	Confidence +95.000%
tPiGF	0.933	0.3390								
tPiSV	0.861	0.4237	33	0.0721	0.1723	2.405	32	0.022	0.0110	0.1332

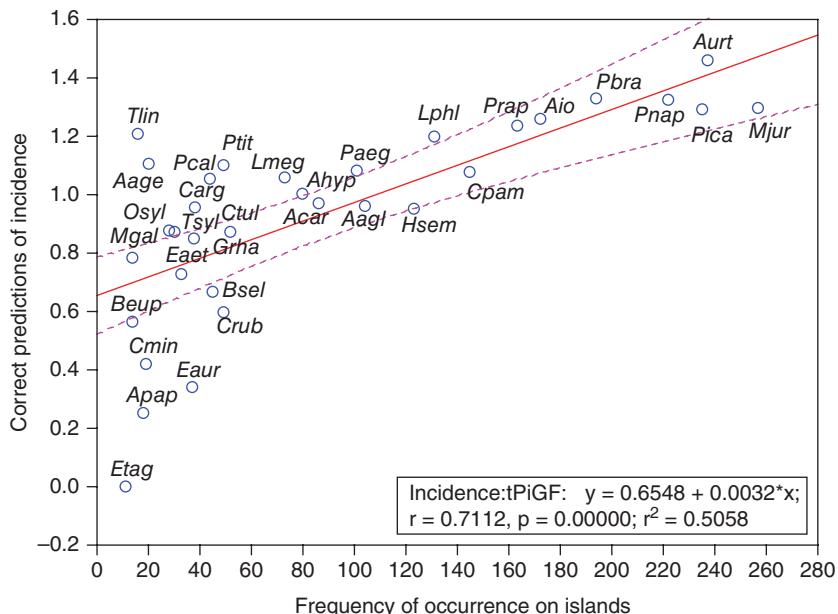

E. Relationship of Correct Predictions of Island Incidences for 191 Islands (with at least two of three migrant markers: Ccro, Vata, Vcar) from Geography and Potential Sources with the Frequency of Occurrences of Species over 910 Islands.

Predictions of correct incidences (from geography and potential source influence) are closely related to the incidences (frequency of occurrences) of species over all 910 islands in the file. The greater the incidence, the greater is the power of logistic equations to correctly predict recorded incidences in the model file of 191 islands. At the lower end, however, there is a wider scatter of species about the regression line, indicative of poorer predictive ability for these species. Those below the regression line are not well predicted at all and as neither geography nor source influences are very successful (fail to correctly predict more than 50% of incidences) then other factors are involved, particularly habitat components or sampling issues.

With *E. tages*:

When the residuals from the above graph are dichotomized (above and below the regression line) they differ significantly with regard to changes in distribution cover between 1976 and 2014; those below the line are losing out faster than those above the line.

Mann–Whitney U Test (PredictionversusLoss)

Marked tests are significant at $p < .05000$

	Rank Sum Group 1	Rank Sum Group 2	U	Z	P-value	Valid N Group 1	Valid N Group 2
Loss	149.5000	411.5000	44.50000	-3.21	0.0013	14	19

Species Incidences on Offshore Islands: Logit Regression Analyses
